33 **1 Abstract**

34 **1.1 Executive Summary**

35 The emergence of cloud computing along with virtualization adds additional complexity to
36 software license management for platform vendors, application providers and their customers.

37
38 The increased mobility of workloads and the ability to clone virtualized systems increases the
39 challenge for organizations to track software license compliance associated with the virtualized
40 instances. The mobility of licensed software to public and private clouds makes it more difficult
41 to accurately identify and inventory deployed software, to trace its use and correlate the use to an
42 entitlement. These challenges, however, create an opportunity to address customer pain points
43 and to unlock the value and realize the efficiencies offered by these new virtualized and cloud
44 technologies.

45
46 In order to fully realize the value of virtualization and cloud technologies standards are needed to
47 sufficiently identify licensed software products, and to trace and gather the use of the software
48 and other entitlement metrics across the span of deployments.

49
50 To effectively manage their licensed software product(s) and product usage, customers have the
51 need to:

- 52 • Record and enumerate software product usage. This could encompass what instances,
53 users, CPUs or other measurable units that may be running, where (e.g. whether in an
54 operating system on hardware server, or a virtualized or cloud computing environment),
55 with what device, and by whom (i.e. on which processor of a given hardware server).
- 56 • Uniquely identify the software licensed product(s) associated with a particular usage.
- 57 • Technically express product usage information of licensed product(s) for pre-deployment
58 or reporting purposes. For example, software entitlement metrics requirements in a
59 package such as Open Virtualization Format (OVF).

60 **1.1.1 Scope**

61 To achieve these goals, the Software License Management (SLM) Incubator was created and its
62 [charter](#) approved in December 2010.

63
64 The Incubator was formed to develop recommendations focused on the challenges surrounding
65 software licensing management and to move the industry in a direction to effectively manage
66 licensed software product(s), and work toward interoperable solutions.

67
68 The intent of this work is to be applicable to licensed software. It is applicable to software
69 products that are developed in various ways, including the use of open source software.

70
71 This white paper outlines the technical aspects required to address the requirements, use cases,
72 scenarios and solutions identified. For example:

- 73 • The representation of the identity of a licensable product (i.e. virtual machine instance, on
74 premise product, etc.)
- 75 • How it is associated with a running instance or a particular operating system

- 76 • Who and what (device) are assessing that instance, and
77 • The ability to discover if and where the product instance is running.
78

79 **1.2 Acknowledgments**

80 The authors acknowledge the contributions from the members of the DMTF Software License
81 Management Incubator. The following persons were instrumental in the development of this
82 specification:

- 83 • (Editor) Mr. Howard Hastings, Blazent, Inc.
84 • (Editor) John Parchem, Microsoft Corporation
85 • Mr. Shishir Pardikar, Citrix System Inc.
86 • Sharon Pitt, George Mason University
87 • Arul Murugan Alwar, HP
88 • Dr. Brad Topol, IBM
89 • Mr. Curt Barrentine, JP Morgan Chase
90 • Stephen DiGianno, JP Morgan Chase
91 • Ms. Monica Martin, Microsoft Corp
92 • Winston Bumpus, VMware Inc.
93

94 **1.3 Recommendations**

95 The SLM Incubator has identified four key recommendations for future work. These
96 recommendations seek address the requirements identified in the preceding summary and
97 suggest the development of:

- 98 • Standard for the identity of a licensed product offering
99
100 • Standard format for capturing the core entitlement metric requirements that reflect
101 measurable product use rights,
102
103 • Standard log format and a normative schema to capture the consumption of an
104 entitlement.
105
106 • Describe a process and use cases utilizing the above three standards that enable the
107 automation of the core licensing management use cases and to enable the determination
108 of the state of compliance to the corresponding license terms.
109

110 One intended usage of the above standards is that the product identity and the core metric
111 requirements can be carried in an Open Virtualization Format (OVF) package for use by an
112 automated deployment system or as part of a private or public cloud deployment package.
113

114

115 **2 Common Terminology**

Term	Definition	DMTF Reference	External Reference
Application	Software that provides functions that are required by an IT Service. Each application may be part of more than one IT Service. An application instance can run on one or more computing systems.	CIM_Application System	
Bundle	A grouping of products which is the result of a marketing/licensing strategy to sell entitlements to multiple products as one purchased item. As these are multiple licensed products there may be no way to determine that an individual installed product was purchased as a bundle.	CIM_SoftwareFeature	
Client Software	The part of a client-server Application that the user directly interfaces with. For example: an email client.		
Client Access License (CAL)	A software license that legally permits client computers to connect to server software. CALs apply to either a "device" (as defined in the license agreement) or a "user". A Per-User CAL allows one user to connect to the server software. Any user can connect, but only one user may use a given CAL at any given time. Any number of devices may connect to the server software, but only a set number of users can connect to it at once. A Per device CAL operates in much the same way, but limits connections made by devices, rather than users. One CAL enables one device to connect to and use the server software, regardless of how many users are connecting.		http://en.wikipedia.org/wiki/Client_Access_License
Computing Device	The hardware technology upon which the software is installed or executed.		
Computing System	One or more virtual or physical computing devices including applicable operating system or firmware that support installation and execution of applications.		
Consumer	Consumer is a legal entity that purchases, installs, deploys or uses a product.		
Central Processing Unit (CPU)	An integrated circuit chip installed in a computing device comprised of one or more processors that perform the instructions of a computer's programs. Modern CPUs usually contain on-chip memory referred to as "level 1" cache.		
Data Center	A data center is a physical location that provides computing resources and may contain physical and virtual systems, storage and networking.		
Deployment	The process of installing a service instance in a reserved or prepared environment.	CIM_Action	
Deployment System	The system that installs a software package or appliance.		

Term	Definition	DMTF Reference	External Reference
Entitlement (Software)	Legal ownership of software license use rights as defined through agreements between a software purchaser and the software copyright holder.		
Feature (Software)	A collection of software elements that performs a particular function or role of a software product. This level of granularity is intended to be meaningful to a consumer or user of the application to choose. This concept allows software products or application systems to be decomposed into units that have a meaning to users rather than units that reflect how the product or application was built (i.e., software elements).	DMTF Application Management Model	
Globally Unique Identifier (GUID)	A unique reference number used as an identifier in computer software.		
Guest Software	The software running on a virtual machine, stored on the virtual disks, that runs when a virtual machine is powered on. The guest is typically an operating system and some user-level applications and services.		
Identity	A name that is used to uniquely identify a user or person for the purposes of granting/assigning software use rights. Example might be the username "SmithJ".		
Image	Exact copy of the storage (disk) contents of a computing device for the purposes of recovery or provisioning of a duplicate system. This encompasses the full instantiation of a deployed operating environment, all applications, data and configuration settings.		
Infrastructure as a Service (IaaS)	A service delivery model where the capability provided to the consumer is to provision processing, storage, networks, and other fundamental computing resources where the consumer is able to deploy and run arbitrary software, which can include operating systems and applications. The consumer does not manage or control the underlying cloud infrastructure but has control over operating systems, storage, deployed applications, and possibly limited control of select networking components (e.g., host firewalls).		http://www.nist.gov/manuscript-publication-search.cfm?pub_id=909616
Instance (Software)	An installed copy of a software product or application whose presence can be identified through manual or automated means.		

Term	Definition	DMTF Reference	External Reference
IT Service	A set of related functions provided by IT systems in support of one or more business areas, which in turn may be made up of software, hardware and communications facilities, perceived by the customer as a coherent and self-contained entity. An IT service may range from access to a single application, such as a general ledger system, to a complex set of facilities including many applications, as well as office automation that might be spread across a number of hardware and software platforms.		http://www.knowledgetransfer.net/dictionary/ITIL/en/IT_Service.htm
License (Software)	Legal rights to use software in accordance with terms and conditions specified by the software copyright owner		
Licensee (Software)	A legal entity, typically a person or organization, contractually bound to a given software license agreement that provides rights to use the associated software in accordance with the terms and conditions as specified by the copyright owner.		
Physical Location	A physical place associated with a specific geographical reference.		
Platform	A combination of hardware and software operating environment upon which applications can be installed and operate.		
Platform as a Service (PaaS)	A service delivery model where the capability provided to the consumer is to deploy onto the cloud infrastructure consumer-created or acquired applications created using programming languages and tools supported by the provider. The consumer does not manage or control the underlying cloud infrastructure including network, servers, operating systems, or storage, but has control over the deployed applications and possibly application hosting environment configurations.		http://www.nist.gov/manuscript-publication-search.cfm?pub_id=909616
Processor	The set of logic circuitry within a CPU that responds to and processes the basic instructions that perform the intended functions of a computing device. Modern processors may contain more than one core and/or have multithread capabilities that allow for execution of multiple instructions.		
Product Activation	Activation associates an event that recognizes the intended use of a software product with a specific device or system.		
Product Edition	A specific edition (i.e. a SKU variation) related to a specific version of a licensed software product.		
Product Version	A specific release of a licensed software product.		
Provisioning (Software)	The process of selecting, reserving resources, or creating an instance of a service offering.		

Term	Definition	DMTF Reference	External Reference
Relationship (Software)	A connection or interaction between one or more products, solutions, software components, applications or IT Service. Suites and bundles are clear examples of where knowledge of the relationships involved is important to properly manage a product or solution during packaging, provisioning, or addressing license compliance. A more complex example is an IT Service and its requisite applications, where documenting and maintaining the relationships between all the various elements involved is crucial for proper change and performance management.		
Resource	A generic term that includes IT infrastructure, people, money, hardware components or anything else that might help to deliver an IT Service.		
Server (Software)	The part of a client-server application that the client software interacts with. For example: an email server.		
Service Delivery Model	The approach used to deliver a given service to its intended consumers. As it applies to software, Service Delivery Models vary to address different ways in which software can be sold, managed and accessed, such as Software as a Service vs. software that must be installed by the customer on their own server, etc.		
Service Catalog	Self-service portals and/or eProcurement systems that contain a list of available services and products that can be requested/ordered in an automated manner.		
Software as a Service (SaaS)	A service delivery model where the capability provided to the consumer is to use the provider's application(s) running on a cloud infrastructure accessible from various client devices through a thin client interface such as a web browser (e.g., web-based email). The consumer does not manage or control the underlying cloud infrastructure including network, servers, operating systems, storage, or even individual application capabilities, with the possible exception of limited user-specific application configuration settings.		http://www.nist.gov/manuscript-publication-search.cfm?pub_id=909616
Software Catalog	A subset of the service catalog that contains the list of software titles available for request/order through self-service portals and/or eProcurement systems.		
Software Element	A general term that is used to mean one discrete software part of a more complex software product or application.	CIM_SoftwareElement	
Software Product	One or more applications governed by one license, which may include procedures, documentation and data, commercially available as a single item for a fee to a licensee.	CIM_Product	

Term	Definition	DMTF Reference	External Reference
Software Package	A set of related software components that are combined into a single payload or a distributable installable item. For example, a software package is a set of files that can be used to install software on a computing device and can be distributed via CD or electronic means. An Open Virtualization Format (OVF) package is an example of a package for cloud deployment.		
Software Suite	A set of individually licensable software products or software features, that is combined and licensed as a separate single product.		
Solution	A combination of one or more applications, which may also include one or more computing systems, made available as a single IT Service.	CIM_Application System	
Solution Multiplexing	Correlation of use of multiple individually licensed software components that compose a licensed application. For example, a web tier application with a single sign on to a data tier application may need to track those requests on a user's behalf that result in requests to the data tier		
Stock-Keeping Unit (SKU)	A number or string of alpha and numeric characters that uniquely identify a product. SKUs are often called part numbers, product numbers, and product identifiers, and may be represented by a universal number such as a UPC.		http://www.techterms.com/definition/sku
Thread	In programming, a part of a program that can execute independently of other parts. Operating systems that support multithreading capabilities of processors enable programmers to design programs whose threaded parts can execute concurrently.		
Uniform Resource Identifier (URI)	A string of characters used to identify a name or a resource usually on the internet.		
User	A person who uses an IT service. Users are distinct from customers, as some Customers do not use IT services directly.		
Virtual	As it applies to information technology, not physically existing as such but made by software to appear to do so.		
Virtualization Platform	Infrastructure enabling virtualization provided by a host system that enables the deployment of virtual systems.		
Virtual Machine (VM)	The virtual representation of a computing device including the CPU, memory, controllers, network interfaces, and storage that supports the execution of guest software in a virtualized environment.		

Term	Definition	DMTF Reference	External Reference
Virtual System	A virtual operating system environment that includes virtual machine(s), the operating systems and applications. The virtual system is a computer system operated in a virtualized environment that includes its software running in that environment.		

116
117

118

119 **3 Software Licensing Concepts and Environment**

120 Licensed software products can be packaged or made available in many different ways for a
121 consumer. The variability of packaging and distribution methods increases the complexity to
122 uniquely identify and to track usage for a licensed software product(s). Licensing models,
123 programs, and licensing terms also may influence how a licensed software product is packaged
124 or made available.

125

126 Licensed software products are packaged or made available in some of the following ways:

- 127 • End user acquired products
- 128 • Organizational acquired products
- 129 • Single Executable
- 130 • Single product
- 131 • Suite
- 132 • Server offering
- 133 • Product bundling

134

135 Software products are licensed based on factors such as: its use, the party that will use or access
136 it, on what device, number of processors, amount of system memory, running location, and what
137 other products are required to run it.

138

139 Licensed software products are to be used based on an entitlement(s). Common entitlements
140 include:

- 141 • End User License Agreement (EULA)
- 142 • Site License
- 143 • Subscription
- 144 • Type of use or consumption (personal/business)
- 145 • Client Access License (CAL)
 - 146 ○ Device
 - 147 ○ User
 - 148 ○ Concurrent user
 - 149 ○ Internal, external
- 150 • Instance license
- 151 • License specific to a product

152

153 The use rights for and consumption of a licensed software product are tied to its entitlement. Use
154 rights typically provide boundaries for:

- 155 • Operating System requirements
- 156 • License Life span
- 157 • Transfer rights
 - 158 ○ Computer System
 - 159 ○ Physical Location
- 160 • Number of unique Users
- 161 • Number of Installations
- 162 • Number of unique Devices
- 163 • Maximum number of processors\ virtual processor

- 164 • Maximum amount of system memory
- 165 • Location
- 166 • Type of Device\system (desktop, server, phone, ...)

167

168 Entitlement metric are events that measure the installation and use of a software product
169 instance. Entitlement metrics may be gathered on the consumption of a licensed software product
170 instance. The characteristics of and packaging for a licensed software product are defined to
171 identify and track consumption of that product instance.

172

173 A licensed software product and its constituent components, where applicable, should be
174 normatively identifiable to enable traceability through its lifecycle for identification and
175 consumption purposes to correlate entitlement metrics.

176

177 Today products are delivered to a desktop, through a virtualized environment, from the cloud and
178 through an enterprise data center. The characteristics of and consumption of a licensed software
179 product instance should be traceable regardless of the environment of which it may be made
180 available.

181

182 Application virtualization is where the technology isolates and packages applications in a way
183 that they are dissociated from the underlying machine and operating system. Correspondingly,
184 desktop virtualization is where the technology isolates the entire user experience (or desktop)
185 from a physical machine and makes it available across one or more client devices.

186

187 The characteristics of a licensed software product may be captured in a computable package such
188 as an Open Virtualization Format (OVF) package. OVF 1.1 is a DMTF Standard, and very
189 recently was approved as an ISO/IEC International Standard. OVF is a standard format for
190 packaging virtual appliances or machines. This allows the virtual machine to be more easily
191 moved and deployed across virtualization platforms.

192

193 Licensed software products may also be available or deployed in the cloud. As shown in Figure 1
194 there are currently several acknowledged categories of clouds: private, public, community, and
195 hybrid.

196

- 197 • Private Cloud- A private cloud is one that serves a single organization. Private clouds
198 facilitate security, compliance, and quality of service improvements due to network
optimization and isolation.

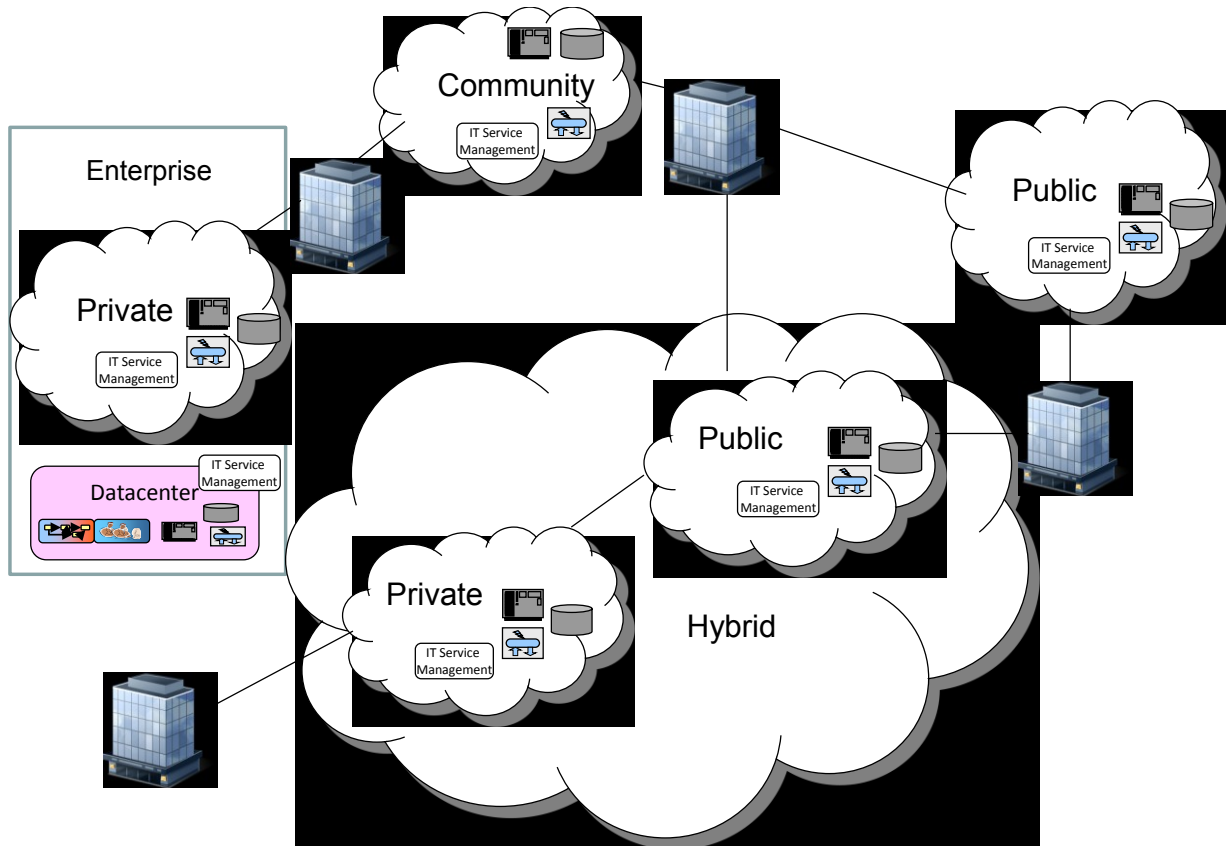

199

- 200 • Public Cloud- A public cloud is one that is available to the general public and is
201 owned by an organization selling cloud services. Public clouds provide efficiencies
through large economies of scale.

202

- 203 • Community Cloud- A Community cloud shares infrastructure between several
 204 organizations from a specific community with common concerns (security,
 205 compliance, jurisdiction, etc.), whether managed internally or by a third-party and
 206 hosted internally or externally. The costs are spread over fewer users than a public
 207 cloud (but more than a private cloud), so only some of the benefits of cloud
 208 computing are realized
- 209 • Hybrid Cloud- A hybrid cloud is a composition of two or more clouds (private,
 210 public, or community) that remain separate and autonomous but allow for data and/or
 211 application portability between themselves via standard or proprietary technologies.

212 The figure evidences the complexity of identifying and tracking consumption for licensed
 213 software product instances through the product lifecycle.
 214
 215

216
 217 Figure 1 Cloud Deployment Environments
 218

219 In the following sections, we identify several key scenarios that further describe the
 220 identification of and consumption for a licensed software product instance through its
 221 lifecycle.
 222

223 4 Scenarios

224 This section describes key entitlement metric scenarios that focus on top level product
225 deployment scenarios. The entitlement metric scenarios can be summarized: What software do I
226 have; who or what is using the software and where and when is the software being accessed. The
227 scenarios are written to illustrate the requirements needed to answer these questions in a
228 normative process across a range of deployment scenarios. The uses cases derived from the
229 deployment scenarios place requirements on software packaging, deployment, installation and
230 upgrade, and runtime logging by the software. These requirements are the focus of this white
231 paper.

232
233 Also note that parts of the included scenarios are outside of the scope of Software License
234 Management Incubator and their inclusion is not an effort to make a recommendation for
235 standardization. They are listed to explore and illustrate the requirements for the data artifacts
236 required to standardize product identification and entitlement metrics.

237
238 The scenarios focus on separate environments with some overlapping requirements.

- 239 1. The packaging and development of software, solutions or applications for deployment in
240 a cloud.
- 241 2. Desktop deployment of software in an enterprise
- 242 3. Software delivered as a service
- 243 4. Application and desktop virtualization
- 244 5. The packaging and installation of software on a server in a data center. It is possible that
245 the data center is an enterprise data center or a cloud data center.
- 246 6. Cloud deployment scenarios

247
248 The packaging and development requirements focus on software identity and a manifest of
249 licensable software within a package. The data center use cases utilizes a software identity
250 artifact, but also focuses on the entitlement metrics to track the “who”, “what”, “when” and
251 “where” of an installed software instance throughout its lifecycle. Entitlement metrics should be
252 tracked, discoverable and available for reporting. The cloud deployment scenarios focus on the
253 additional requirements of tracking software utilization or entitlement metrics in a remote data
254 center. The scenarios are described from the perspective of the described set of actors.

279

4.1 Scenario Actors

A group of actors are identified that may participate in the scenarios defined in this document:

- IT Pro/Administrator
 - a. Software or Asset Administrator: Corporate software assets – match assets against the licenses acquired [Persona: IT Pro]
 - b. System Administrator [Persona: IT Pro]
 - c. Deployment Manager – Deployment on virtual machine [Persona: IT Pro]
- Product Provider
- Procurement Manager [Persona: Business Development Manager]
- Business Manager: Vendor or contract manager [Persona: Business Development Manager]
- Compliance officers
 - a. Compliance Manager: Assesses reports against regulatory, corporate and other requirements (i.e., Business Conduct). Responds to information provided by IT Auditor. Compliance Manager develops set of criteria for IT auditor. [Persona: Business Development Manager]
 - b. IT Auditor (internal) [Persona: Business Development Manager]
 - c. Auditor (external): Reviews Compliance Manager’s output and verifies or certifies the results, and approves the compliance plans.
- Security Manager: Access control [Persona: none defined]
- Service Manager [Persona: IT Pro]
- End user

280

281 4.2 Usage Scenarios

282 The usage scenarios focus on the usage of licensed software products. Usage scenarios are identified for
283 on-premise and enterprise or cloud data centers.

284 4.2.1 End user scenarios

285 The end user scenarios are a set of scenarios that focus on software used on a desktop computer, terminals
286 or mobile devices. Multiple core scenarios are in practical use today:

- 287 • On-premise deployment of end user requested desktop software from a software offering catalog
- 288 • End user use of virtual applications streamed from a server onto a client device.
- 289 • End user access of server resources.
- 290 • End user use of a virtualized desktop.

291 4.2.2 End User Request Software for a Desktop System

292 An end user requests software from an enterprise software catalog for use on a desktop target system. The
293 software is licensed by the enterprise and available for use. The software is provided, installed and then
294 used by the end user.

295

296 Entitlement, utilization, and product metrics are gathered from both the software catalog and the user's
297 desktop system to track the lifecycle of the software instance including additions, upgrades and removal.

298 Refer to 8 Appendix A for a detailed look at the use cases and the need for entitlement metrics across the
299 life cycle of a product for this scenario.

300 4.2.3 End User Entitlement to Software use via a Licensing Server

301 An enterprise acquires software and a number of licenses for a software product and ties the acquired
302 licenses to a licensing server.

303

304 End user software is deployed and installed through any means, CD, software download or preload in an
305 image file. As part of installation a license server is discovered or the user is prompted to provide the
306 address of the license server.

307

308 When a client uses the software the software connects to the license server, and requests a use license.

- 309 • If the customer has a "Concurrent User License" and the software is available for use, the client is
310 granted access.

- 311 • If the customer has "Per User/Device License" and if a license is available, the client is granted
312 access.

- 313 • If the license server is not found, the client is either not allowed to run the software or given a
314 temporary use license.

315

316 Entitlement metrics should be gathered on the acquisition and release or expiry of a license and the
317 products use. Entitlement metrics are also generated on the licensing server.

318

319 The license is validated per usage. User access is based on consumption (per-use).

320 4.2.4 End User Access to Software as a Service

321 Software may also be provided through an application delivery system or appliance which provides
322 enterprise level services to an end user commonly through a web based interface. The software is
323 delivered as a service to the end user.

324

325 In this scenario the software mainly exists on the servers providing the service. Often a thin software
326 client (i.e. applet, or ActiveX control) is downloaded or installed on the client. Entitlement metrics are
327 gathered on the servers providing the service.

328 **4.2.5 End User use of virtualized application**

329 Stateless client application can be virtualized on a server and run on demand by a user and
330 delivered to the user through a remote console protocol like Microsoft Remote Desktop Services
331 or Citrix XenApp. In these cases it is assumed that the license tracking would be performed on
332 the server that is hosting the application.
333

334 **4.3 Packaging and Deployment Scenarios**

335 Licensed software products can be packaged to form solutions, suites, bundles and virtual appliances. To
336 ease the burden of licensing management the deployment scenarios place requirements on the software
337 developer, systems integrator or software vendor to include the product identification for each licensable
338 product in the package in a normative and machine readable format. The following scenarios illustrate the
339 value of a normative list of licensable products and required entitlement metrics contained in the software
340 deployment package.

341 **4.3.1 Packaging for data center deployments**

342 Broader use of virtualization in enterprise data centers or private clouds has changed the typical data
343 center deployments from an install in place or provisioning of software on a server to the deployment of
344 fully provisioned images. Without the knowledge of the licensed software contained in the image it is
345 hard for the IT Pro to assure licensing compliance. A normative manifest in the deployment package
346 could contain both a list of the installed products and the metric requirements for those products to
347 complete the following scenario.
348

349 A standards compliant OVF deployment package is scheduled for deployment in a data center. Before
350 deployment the software administrator opens the package and extracts the product identification section
351 from the package and if available any packaged license entitlements to assure that the proper entitlements
352 are available to comply with the licensing requirements of the products in the package.
353

354 Based on the available entitlements for each product the software administrator either appends to an
355 existing set of entitlement metric requirements or places an entitlement metric requirements data structure
356 into the package for deployment by the deployment manager.

357 **4.3.2 Cloud deployment**

358 Three cloud deployment scenarios have been identified.
359

360 Product provider packages a solution targeted at a cloud deployment that contains multiple
361 separately licensed products. Included in the package is a manifest that contains the software
362 Identification of all of the products contained in the product.
363

364 Deployment manager receives a packaged solution to deploy into an enterprise private cloud.
365 Before deployment the licensed products in the package are inventoried and checked against
366 available entitlements to assure license usage compliance. The deployment manager determines
367 whether to constrain a deployment, migration or movement of a package.
368

369 An IT Pro wants to move a line of business application from a set of dedicated servers to the
370 enterprises private cloud. The IT Pro queries each of the servers to obtain a list of the software

371 products contained in the servers that are used in the application. The IT Pro includes this list in
372 the application package being developed to deploy the application in the private cloud. The IT
373 Pro also delivers the list to the asset manager to obtain free up or transfer the entitlements that
374 are required to run the package in the private cloud. IT Pro also places a data structure into the
375 package that includes the entitlement metric requirements before deploying the package on the
376 cloud service.

377 **4.3.3 Product deployment in an enterprise data center**

378 Three enterprise data center scenarios have been identified.

379
380 Compliance Manager takes an inventory of all the licensable software products in a Data Center.
381 For each of the discovered products, entitlement metrics are harvested from the system logs
382 identifying life cycle and usage events for the product. The Compliance Manager correlates the
383 lifecycle and usage logs against the relevant entitlements to assure that the data center is in
384 compliance with the entitlements for the products. This includes inventory usage for product
385 instances accessed indirectly through another licensed software product on behalf of a user.

386
387 The Software Administrator uses the correlation between the entitlements and the installed
388 products, and entitlement metrics to forecast, adjust the continuing license requirements. For
389 example, product usage and activations could determine the necessity to adjust licensing
390 requirements.

391
392 An IT Pro set up an automated system to track product usage against a set of entitlement policies
393 set by the Software Administrator. An example is a service that requires a Client Access License
394 (CAL) per unique user or client device. The IT Pro registers for the relevant indications (events)
395 based on the standard set of entitlement metrics delivered by each software product instance.
396 Based on the dynamic usage events received each month the IT Pro is able to deliver a report to
397 the Software Administrator with recommendations to increase or decrease the available
398 entitlements or the type of entitlement required. For example, the IT Pro uses an automated
399 system to differentiate per-processor or per-server product usage for the same license type and
400 different entitlement metrics. Or, the IT Pro tracks product usage based on access to domain and
401 member servers irrespective of where the usage occurs.

402 **4.3.4 Datacenter/Server software deployment**

403 During deployment of software or a packaged software solution, suite, or bundle, a deployment manager
404 is able to discover the products contained in the package and the required entitlement metrics before the
405 installation on the server(s). Entitlement metrics requirements are expressed in a standard way.

406
407 The Deployment Manager uses the available metric requirements to select a suitable server and/or create
408 a virtual machine template that matches the entitlement metrics requirements.

409
410 When a licensed software product(s) are deployed, an artifact for each product is created that captures the
411 relevant entitlement metrics relating to the environment into which the software is deployed (i.e. location,
412 hardware definition, and VM definition).

413
414 As part of the deployment the Deployment Manager may also configure any settable system
415 configurations parameters that are expressed in the entitlement metric requirements as packaged by the
416 software asset manager.

417 **4.3.5 Administrator Deployed Software on Desktop System**

418 A software administrator deploys software products to an individual or a group of desktop
419 system. Entitlement metrics are generated when the software is actually deployed, used or
420 removed from a system. An example would be an IT managed installation of an antivirus product
421 across an enterprise's desktop systems.
422

423 **5 Management Data Artifacts Requirements**

424 To support the monitoring and management of relevant events related to software entitlements,
425 events for the installed instance should be logged according to the defined standards for
426 entitlement metrics. The Software Usage Lifecycle section lists the relevant but not exhaustive
427 list of software life cycle events that a system should capture.

428 **5.1 Software Usage Lifecycle**

429 To support the monitoring of relevant events related to software entitlements these events for the
430 software instance should be logged according to a to be defined standard for entitlement metrics.
431 The following list shows the relevant software life cycle events that should be captured.

- 432 • Request for software
- 433 • Acquisition of software and/or entitlement
- 434 • Addition to software offering catalog or software made available for use (consumption).
- 435 • Deployment or installation
- 436 • Product use
- 437 • Application migration
- 438 • VM migration
- 439 • Removal
- 440 • Modification of the software instance
- 441 • Upgrade or Downgrade
- 442 • Retirement

443
444 An example of a detailed description of a complete lifecycle, the end user request for software
445 scenario is included in Section 8 Appendix A. The following two sections Product Identification
446 and Entitlement Metric Requirements describe the relevant aspects that should be captured in
447 each event.

448 **5.2 Artifact Overview**

449 **5.2.1 Product Identification**

450 A licensed software product instance should be identifiable by a normative set of properties. This
451 structure should contain all of the information required to completely identify the software
452 product and optionally to describe the entitlement metrics that the product generates through its
453 life cycle. For example:

- 454 • Vendor
- 455 • Software ID
- 456 • Software ID Type
- 457 • Product Title
- 458 • Product Category
- 459 • Product Family

- 460 • Edition
- 461 • Release Date
- 462 • Software version
- 463 • Software edition
- 464 • Version Type
- 465 • Patch Level
- 466 • Product Dependencies
- 467 • Entitlement Metric Requirements[] (usage, user, processors, OS version, operational state
- 468 ...)
- 469 • Certificates[]
- 470 • Security Token
- 471

472 5.2.2 Entitlement Metrics

473 Entitlement metrics capture the relevant measureable or discoverable events in a system that
474 relate to the licensing of a product.

- 475 • Product identification as described in section 5.2.1 .
- 476 • The environment, unique users, devices, and usages related to the licensed software
477 product instance
 - 478 ○ Number and type of virtual processors\cores
 - 479 ○ Amount of memory
 - 480 ○ Number and type of underlying hardware processors\cores
 - 481 ○ Timestamp
 - 482 ○ Administration domain
 - 483 ○ File location of binaries\executable
 - 484 ○ User Identity,
 - 485 ○ User privilege
 - 486 ○ privilege level ,
 - 487 ○ Client device identity and\or
 - 488 ○ server identity
 - 489 ○ Tenant
 - 490 ○ Server or device type
 - 491 ○ Operating system Identity
 - 492 ○ Event type (reflect the life cycle)
 - 493 ▪ Use
 - 494 ▪ Operation state change (running, paused, stopped ...)
 - 495 ▪ Installation
 - 496 ▪ Uninstall
 - 497 ▪ Migration departure
 - 498 ▪ Migration arrival
 - 499 ▪ Upgrade/
 - 500 ▪ Servicing
 - 501 ▪ ...
 - 502 ○ ...
- 503 • Usage Metrics (running time ..., processor time, memory usage, timer based metrics)
- 504

505

506 **6 Relevant Standards**

Organization	Specification	Date	Description
DMTF	DSP0140 Application White Paper	June 2003	The CIM Application Management Model is an information model that describes the details commonly required to manage software products and applications. This model can describe applications with various structures – ranging from standalone desktop applications to a sophisticated, multi-platform distributed, Internet-based application. Likewise, the model can be used to describe a single software product as well as a group of interdependent software products that form a business system.
DMTF	DSP0243 Open Virtualization Format (OVF)	January 2010	The Open Virtualization Format (OVF) Specification describes an open, secure, portable, efficient and extensible format for the packaging and distribution of software to be run in virtual machines.
DMTF	DSP1054 1.2.0 Indications Profile	June 2011	The Indications Profile defines the CIM elements that are used to subscribe for indications of unsolicited events, to advertise the possible indications, and to represent indications used to report events in a managed system.
OASIS	Solution Deployment Descriptor (SDD)	Sept. 2008	This specification defines schema for two XML document types: Package Descriptors and Deployment Descriptors. Package Descriptors define characteristics of a package used to deploy a solution. Deployment Descriptors define characteristics of the content of a solution package, including the requirements that are relevant for creation, configuration and maintenance of the solution content. The semantics of the descriptors are fully defined, allowing software implementations to precisely understand the intent of the descriptor authors and to use the information provided in the descriptors to support solution deployment.
IETF	Application Management MIB	May 1995	This specification defines an experimental portion of the Management Information Base (MIB) for use with network management protocols in the Internet Community. In particular, it defines objects used for the management of applications. This MIB complements the System Application MIB, providing for the management of applications' common attributes which could not typically be observed without the cooperation of the software being managed
ISO/IEC	19770-2:2009 Software Identification Tag Standard	2009	ISO/IEC 19770-2:2009 establishes specifications for tagging software to optimize its identification and management.

507

508

509

510 **7 Standards Currently Under Development**

511

ISO/IEC	19770-3 Software Entitlement Tag Standard	Under development	ISO/IEC 19770-3 focuses on capturing and defining the information necessary to describe how software may be used, known as the entitlement. This standard will provide a framework and criterion of measurement for creating unambiguous definitions of entitlements.
---------	---	-------------------	---

512

513

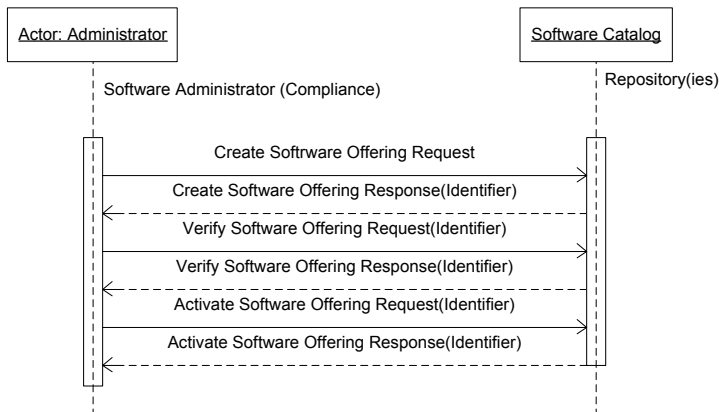

514 **8 Appendix A**

515 The following are the use cases for just one of the above scenarios, automated end user requested
 516 software for their desktop system. The diagrams are shown only as an illustration of the type of
 517 interactions and the metrics required completing the scenario and track and managing the
 518 software licenses involved in the scenario. The scenario and the use cases described were used to
 519 determine the necessity and the requirements for software license management. Although this
 520 use case addresses a desktop deployment scenario, many of the use cases around the usage
 521 metrics and licensable events are true for the server scenarios that were discussed in the
 522 incubator.

523

524 **Make Software Available**

525 An administrator adds a software offering to a software catalog and makes it available for
 526 request. An administrator may verify the software offering and activate it in the software
 527 catalog.

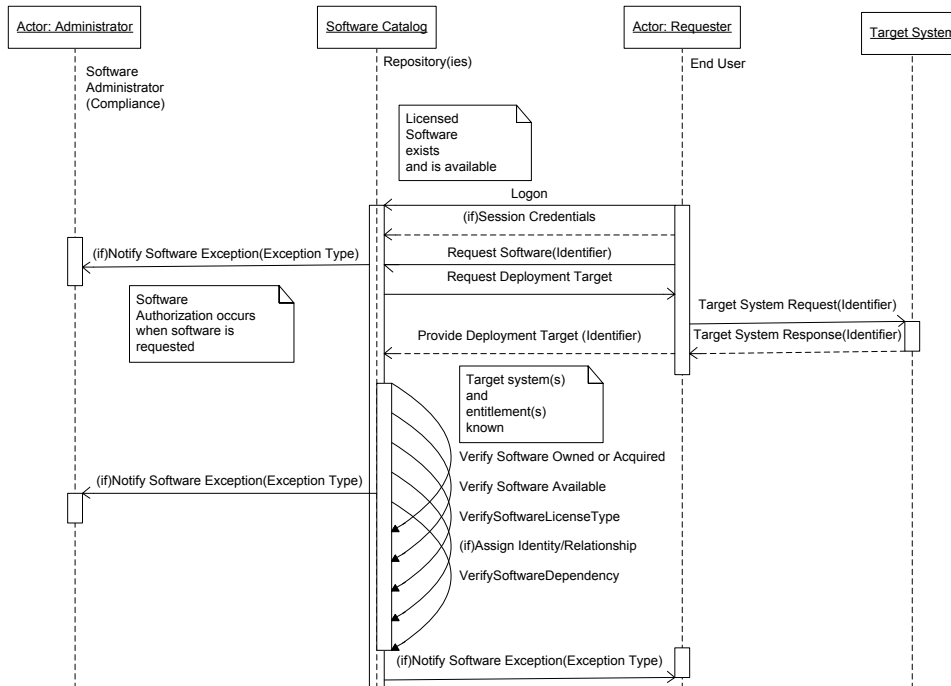

528

529

530 Request Software

531 A requestor (actor) requests software from a software catalog to deploy to a desktop system. The
 532 software request and deployment environment are used to complete the request. Software should
 533 be owned and available in the software offering to fulfill the request. As this is a licensable
 534 event, other licensing and software dependency checks are made before the software request can
 535 be completed. An authorization occurs when the request for software and other checks are made.

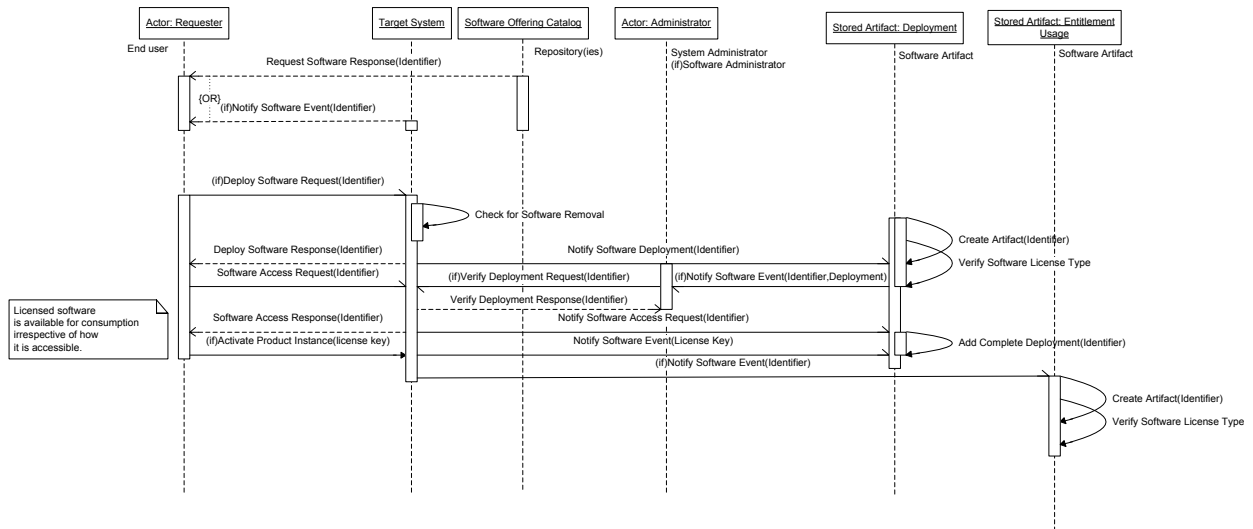

536
 537

538
539
540
541
542
543

Deploy Software

After a software request is complete, software is delivered to the desktop system for deployment. Deployment can be by manual or automated means. Entitlement metrics are captured throughout the deployment of the software. A licensing key may be required to activate the software instance.

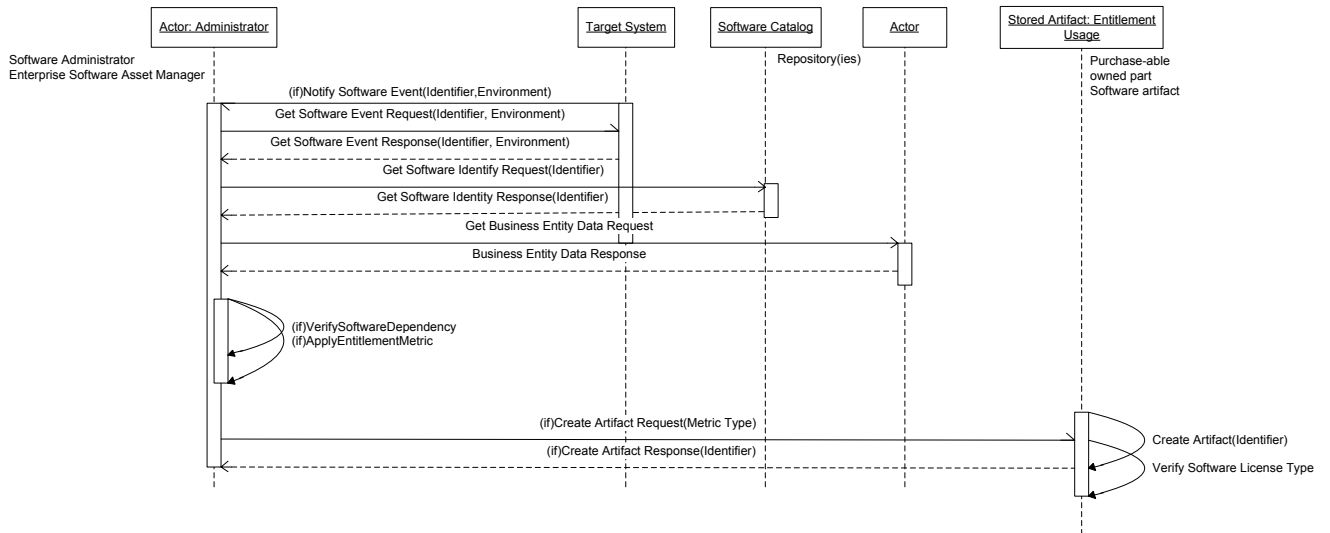

544
545

546
547
548
549
550
551
552
553

Identify Relationship

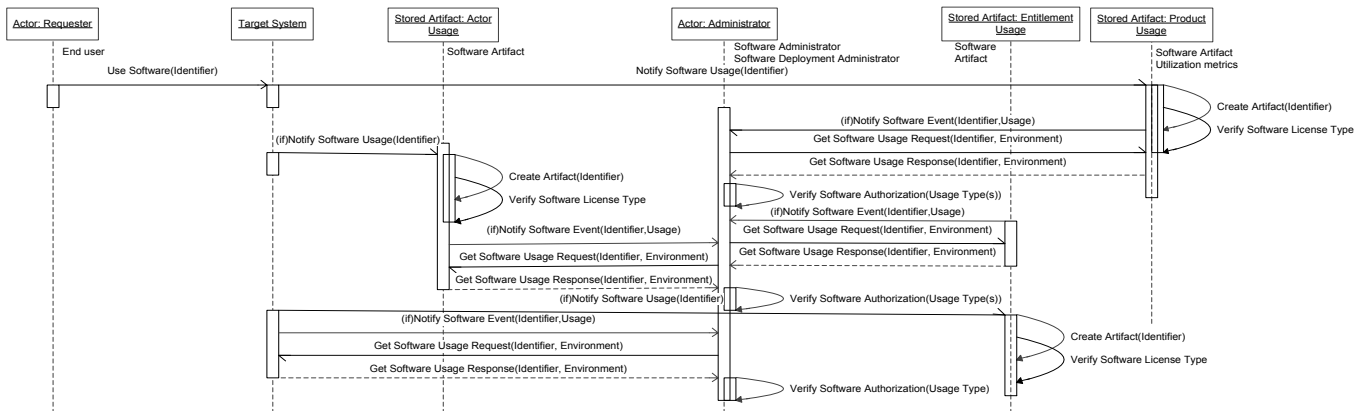

A software request, and deployment and access are related to and accounted for by a business entity. Entitlement metrics are created and captured on the software instance once the business entity-software instance relationship is set. The business entity is the consumer of the entitlement. Creating the relationship between the software request, the business entity, and the entitlement could occur in parallel to or in conjunction with other phases (i.e. Request Software, Deploy Software).

554
555
556
557
558

Use Software

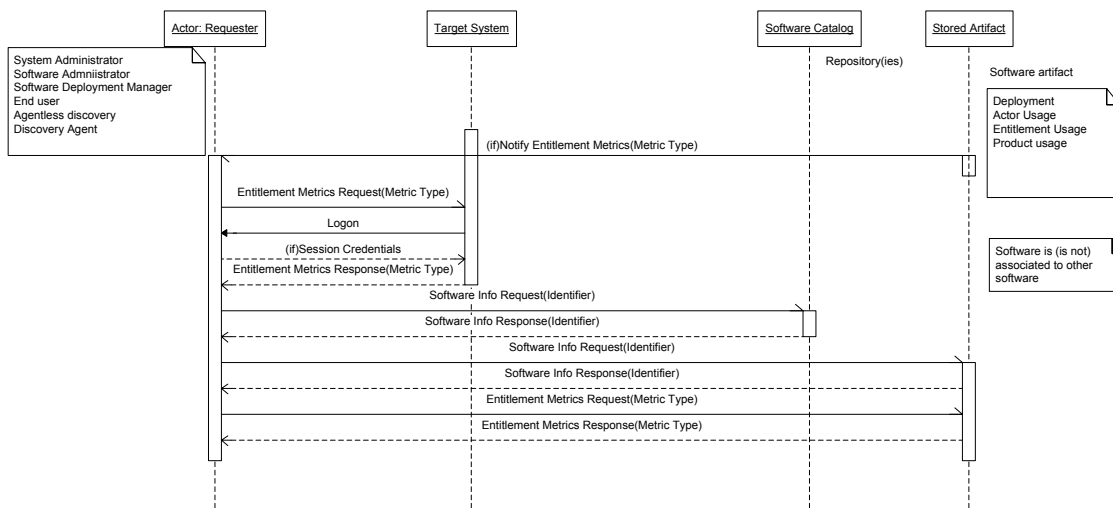

Entitlements metrics are captured when a software instance is accessed and used for the lifecycle of the software instance.

559
560

561 Change Software
 562 Requests to change a software instance may occur during its lifecycle and metrics captured on
 563 licensable events. Software may be added (i.e. for upgrade or new) or software removed (i.e. for
 564 replacement). A software upgrade may require a new software request and deployment, and
 565 removal of existing software. Such a request may result in a change in entitlement.
 566

567 Discovery Reporting
 568 The Entitlement metrics are available for discovery and reporting. The metrics are created at key
 569 points in the software instance lifecycle - at deployment, by actor usage, when an entitlement is is
 570 used, and if the software instance is used or accessed (utilization).

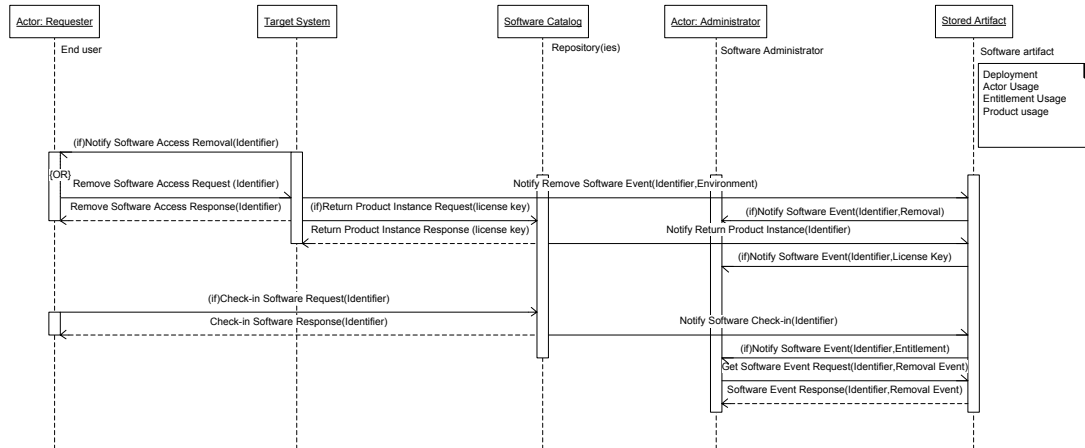

571
 572
 573

574

575 Remove Software

576 The software instance may be retired or returned to the software offering catalog when a request
 577 is made to remove that instance. The software may be returned to the software catalog and made
 578 available for re-deployment. If required, licensing keys may also be returned. The entitlement
 579 metrics are created to reflect the removal of the software instance and the associated entitlement.

580

581
